INTRODUCTION TO MOTE RUNNER

MOTE RUNNER

- An OS and a runtime and development environment for WSN
- · Key features:
 - · Support for RT constraints & energy awareness
 - · Portability thanks to a VM that abstracts the HW
 - · Event oriented programming paradigm
 - · High level coding (Java C#)
 - · Debugging & simulation environments
- · It's still in beta and is evolving towards IoT

MOTE RUNNER OPERATING SYSTEM

- Mote Runner system provides:
 - A Virtual Machine for executing byte codes
 - · An Operating System for:
 - organizing access to different devices
 - scheduling the various activities

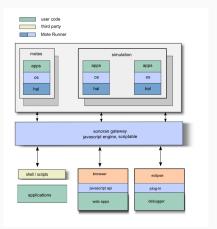

DEVICE MODEL

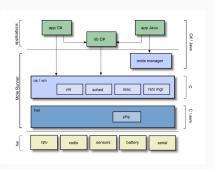

• The OS assumes that all devices have the following states

- · The OS manage implicitely most of the state changes:
 - Makes sure that the device ramp up happens before the requested time
 - · Keeps device in states with the lowest energy consumption
 - Application, however, can put devices into the states CLOSED, OFF and STDBY

MOTE RUNNER

MOTE RUNNER - V.11, V.13 BETA

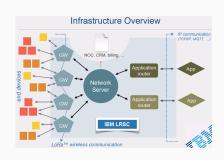

- · They support IEEE 802.15.4
 - exposing a low radio level API that can be used to implement custom MAC layer
 - dropping messages with header structure not 802.15.4 compliant in the radio stack
- · Offer Hopi
 - · A multi-hop data gathering protocol
 - Used to collect data from motes setting automatically a tree network

MOTE RUNNER - V.17.1.8C (LATEST)

- · Supports only two platforms: IMST & Blipper
- · It's based on a different radio layer: LoRa™
- · It offers a build-in MAC layer: LRSC Low Range Signaling & Control
 - · It supports only a network topology: the LRSC one
 - The offered API is poor since the radio is hidden in the firmware (not compatible with previous versions)

LRSC - ARCHITECTURE

- · Gateways (GW) are connected to server on IP
- Motes comunicate with server in tunneling TCP/UDP over IP
- Motes comunicate with GW with LoRa single-hop

IBM LRSC

- The Long Range Signaling and Control (LRSC) system is a network infrastructure which relies on LoRa™, modulation technology developed by Semtech for wireless bidirectional communication over distances of up to 15 km in semi-rural environments and up to five km in dense urban environments.
- · All communication is generally bi-directional, although uplink communication from end devices to the network server is strongly favored, and is based on LoRa.

LRSC NETWORK SIMULATION

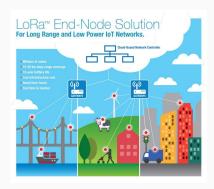

The Mote Runner SDK ships with:

- LoRa Mac library providing an API for accessing a LRSC network.
- · LIP shell interface to control the Mac from the Mote Runner shell MRSH.

The main constraint for our intial purpose depends on the fact that the end devices cannot communicate directly. Any message should be sent over the LRSC network.

LORATM

- LoRa™Alliance
 - Target: IoT, machine-to-machine (M2M), smart city, and industrial applications
 - Intiated to standardize Low Power Wide Area Networks (LPWAN)

LORATM

LoRa™Technology

- LoRaWAN pledeges to extend the radio range by 10x while using only one third of the power used by competing solutions
- · Star (of stars) topology
- Gateways relay messages between end-devices and a central network server
- · Communication between end-devices and gateways is spread out on different frequency channels and data rates.
- · Data rates: 0.3 50 kbps

LORATM

- · ...and more
 - · adaptive data rate (ADR)
 - secure communication (on network and application layers and end-point device key)
 - · three classes of end-point devices.
 - · More info on http://lora-alliance.org/

MOTE RUNNER - CONCLUSION

- · For the purpose of this work (TAKS & WIDS):
 - MR allows dynamic reprogramming of motes with a control server using WLIP
 - · v.17.1.8c is not suitable
 - LoRa is available only for a limited number of platforms (until now!)
 - · LRSC doesn't permit to customize the MAC behaviour
 - · The radio is not exposed
 - · v.11, v.13 are better choices:
 - · radio interface could be used to implement an 802.15.4 MAC with TAKS support
 - · this MAC could be used to build upper layer with WIDS
- This does not exclude a future integration with LoRa-LRSC

TESTING MOTE RUNNER

POINTS TO EXPLORE

- · MR v.13 offers:
 - · Radio interface IEEE 802.15.4 compliant
 - · Hopi
 - · A simulation environment IRIS friendly
 - · Many nice features (Debugger, Logger and so on)

PROGRAMMING THE RADIO

- · com.ibm.saguaro.system.Radio
 - This is a generic class in the IBM saguaro system to use the device radio
 - · It offers a low level API with the following functionality:
 - · open: opens the radio, once opened no other assembly can use it
 - · close: releases the radio so that others can use it
 - setter and getters for channel and network parameters (addresses, panid...)
 - startReceive: listens the channel (in one of the many receiption mode)
 - · transmit: begin to transmit a pdu

TRANSMISSION & RECEPTION

- · These operations require much attention:
 - The radio permits to transmit every type of pdu, but it's possible to receive only packets with 802.15.4 well formed headers
 - It's also possible to receive in promiscuous mode to sniff for every packet, but this exposes to interferences
- · Each mote mantains 3 addresses:
 - · a 16-bit PAN identifier
 - · a 64-bit extended address that uniquely identifies a mote
 - a 16-bit short address that's application and protocol specific

TRANSMISSION & RECEPTION

1 1 1 1					# of bytes per field
FCF FCA SEQNO	DSTPAN DSTADDR	SRCPAN SRCADDR	aux.security	payload	field name
<a< td=""><td>ddressing fields</td><td>></td><td></td><td></td><td></td></a<>	ddressing fields	>

			SEC	PEND	ACKRQ	NSPID	RFU	field name:

Figure 2: Frame Control Flags

Figure 3: Frame Control Address Flags

TX/RX REAL AND REAL TIME CONSTRAINTS

- It's possible to operate in many different ways with regards to real time constraints:
 - · It's possible to receive/transmit ASAP (As Soon As Possible) or EXACTLY at the specified time or ...
 - · Rx/Tx require a start operation time and an end one
 - MR manages autonomously all warm up and ramp up to make the device ready at the specified time
 - The device turn off at the end and an event is raised to be managed with delegation
 - · If the device cannot be ready at the specified time or an error occurs an error reports this status
